

PRACTICAL NO: 4

AIM:

1. Adam is working in an IT company. He has been given a task to reduce the load of a system by killing some of the processes running in the LINUX operating system. Which commands will he use to complete the given task with the help of the following operation?

- Kill Processes by name
- Kill a process based on the process name
- Kill a single process at a time with the given process ID

2. Write a program for process creation using C

- Orphan Process
- Zombie Process

3. Create the process using fork () system call

- Child Process creation
- Parent Process creation
- PPID and PID THEORY:

This practical focuses on understanding process management in the Linux operating system. A process is a program in execution, and Linux manages multiple processes through multitasking. Processes are created using the fork() system call, which forms parent and child processes. Each process is identified using PID and PPID to maintain hierarchy. The experiment also demonstrates process execution, termination, and the use of system calls like exec() and wait(). It further explains special cases such as orphan and zombie processes in Linux

PERFORMANCE:

- Kill Processes by name
- Kill a process based on the process name
- Kill a single process at a time with the given process ID

COMMAND:

shreyansh123@DESKTOP-1UJ64CI: ~

```
shreyansh123@DESKTOP-1UJ64CI:~$ ps -ef
UID          PID    PPID  C   STIME TTY          TIME CMD
root           1         0  0   14:59 ?           00:00:00 /init
root           7         1  0   14:59 tty1        00:00:00 /init
shreyan+      8         7  0   14:59 tty1        00:00:00 -bash
shreyan+     62         8  0   15:02 tty1        00:00:00 ps -ef
shreyansh123@DESKTOP-1UJ64CI:~$
```

```
shreyansh123@DESKTOP-1UJ64CI:~$ ps -ef |grep firefox
shreyan+     64         8  0   15:03 tty1        00:00:00 grep --color=auto firefox
shreyansh123@DESKTOP-1UJ64CI:~$ ps -ef |grep firefox
shreyan+     66         8  0   15:03 tty1        00:00:00 grep --color=auto firefox
shreyansh123@DESKTOP-1UJ64CI:~$
```

```
shreyansh123@DESKTOP-1UJ64CI:~$ kill 9407
-bash: kill: (9407) - No such process
shreyansh123@DESKTOP-1UJ64CI:~$ pkill firefox
shreyansh123@DESKTOP-1UJ64CI:~$
```

2. Write a program for process creation using C

Orphan Process:

An orphan process is a child process whose parent process terminates before the child finishes execution. The orphan process is adopted by the init or system process.

➤ orphan.c :

➤ output:

```
shreyansh123@DESKTOP-1UJ64CI: ~  
shreyansh123@DESKTOP-1UJ64CI:~$ nano orphan.c  
shreyansh123@DESKTOP-1UJ64CI:~$ gcc orphan.c -o orphan  
shreyansh123@DESKTOP-1UJ64CI:~$ ./orphan  
Parent exiting...  
shreyansh123@DESKTOP-1UJ64CI:~$ Child Process  
PID = 78  
PPID = 1 (Parent is init)
```

```
#include <stdio.h>  
#include <unistd.h>  
  
int main() {  
    pid_t pid = fork();  
  
    if (pid == 0) {  
        // Child  
        sleep(5);  
        printf("Child Process\n");  
        printf("PID = %d\n", getpid());  
        printf("PPID = %d (Parent is init)\n", getppid());  
    } else {  
        // Parent  
        printf("Parent exiting...\n");  
    }  
  
    return 0;  
}
```

- **Zombie Process**

A zombie process is a child process that has completed execution but still remains in the process table because its parent has not read its exit status.

➤ **Zombie.c :**

➤ **Output:**

```
shreyansh123@DESKTOP-1UJ64CI: ~  
shreyansh123@DESKTOP-1UJ64CI:~$ nano zombie.c  
shreyansh123@DESKTOP-1UJ64CI:~$ gcc zombie.c -o zombie  
shreyansh123@DESKTOP-1UJ64CI:~$ ./zombie  
Child exiting...  
Parent still running...  
shreyansh123@DESKTOP-1UJ64CI:~$
```

```
#include <stdio.h>  
#include <unistd.h>  
  
int main() {  
    pid_t pid = fork();  
  
    if (pid == 0) {  
        // Child  
        printf("Child exiting...\n");  
    } else {  
        // Parent  
        sleep(10); // Parent does not call wait()  
        printf("Parent still running...\n");  
    }  
  
    return 0;  
}
```

3. Create the process using fork () system call

- Child Process creation
- Parent Process creation
- PPID and PID

Process:

A process is an instance of a program that is currently being executed in the operating system. It includes program code, data, stack and system resources.

Process ID (PID):

Process ID (PID) is a unique numerical identifier assigned by the operating system to each running process for identification and management.

Parent Process:

A parent process is a process that creates one or more child processes using system calls such as fork().

Child Process:

A child process is a newly created process that is generated by a parent process and executes independently.

Parent Process ID (PPID):

PPID shows the process ID of the parent of a running process.

- fork_demo:

- Output:

shreyansh123@DESKTOP-1UJ64CI: ~

```
shreyansh123@DESKTOP-1UJ64CI:~$ nano fork.c
shreyansh123@DESKTOP-1UJ64CI:~$ gcc fork.c -o fork
shreyansh123@DESKTOP-1UJ64CI:~$ ./fork
Child Process
Parent Process
PID = 101
PID = 100
PPID = 100
Child PID = 101
shreyansh123@DESKTOP-1UJ64CI:~$
```

```
GNU nano 0.2
#include <stdio.h>
#include <unistd.h>

int main() {
    pid_t pid;

    pid = fork();

    if (pid < 0) {
        printf("Fork failed\n");
    }
    else if (pid == 0) {
        // Child process
        printf("Child Process\n");
        printf("PID = %d\n", getpid());
        printf("PPID = %d\n", getppid());
    }
    else {
        // Parent process
        printf("Parent Process\n");
        printf("PID = %d\n", getpid());
        printf("Child PID = %d\n", pid);
    }

    return 0;
}
```

4. Infinite loop process:

An infinite loop process is a process that runs continuously without termination until it is manually stopped by the user or system.

```
shreyansh123@DESKTOP-1UJ64CI: ~  
shreyansh123@DESKTOP-1UJ64CI:~$ fork_loop.c  
fork_loop.c: command not found  
shreyansh123@DESKTOP-1UJ64CI:~$ nano fork_loop.c  
shreyansh123@DESKTOP-1UJ64CI:~$ gcc fork_loop.c -o fork_loop  
shreyansh123@DESKTOP-1UJ64CI:~$ ./fork_loop  
Parent created Child 1 | Child PID = 119  
Child 1 | PID = 119 | PPID = 118  
Parent created Child 2 | Child PID = 120  
Child 2 | PID = 120 | PPID = 118  
Parent created Child 3 | Child PID = 121  
Child 3 | PID = 121 | PPID = 118  
shreyansh123@DESKTOP-1UJ64CI:~$
```

```
GNU nano 7.2 loop.c *  
#include <stdio.h>  
#include <unistd.h>  
  
int main() {  
    while (1) {  
        printf("Running...\n");  
        sleep(1);  
    }  
    return 0;  
}
```

Stopped the infinite loop:

[illegible]
